Learning Goals

- Formulate a real-world problem as a constraint satisfaction problem.
- Trace the execution of the backtracking search algorithm.
- Verify whether a constraint is arc-consistent.
- Trace the execution of the AC-3 arc consistency algorithm.
- Trace the execution of the backtracking search algorithm with arc consistency.

Example

Example 4.9. Suppose the delivery robot must carry out a number of delivery activities, a, b, c, d, and e. Suppose that each activity happens at any of times 1, 2, 3, or 4. Let A be the variable representing the time that activity a will occur, and similarly for the other activities. The variable domains, which represent possible times for each of the deliveries, are

 $\begin{array}{l} dom\left(A\right)=\{1,2,3,4\}, \ \ dom\left(B\right)=\{1,2,3,4\}, \ \ dom\left(C\right)=\{1,2,3,4\}, \\ dom\left(D\right)=\{1,2,3,4\}, \ \ dom\left(E\right)=\{1,2,3,4\}. \end{array}$

Suppose the following constraints must be satisfied:

 $\{ (B \neq 3), (C \neq 2), (A \neq B), (B \neq C), (C < D), (A = D), (E < A), (E < B), (E < C), (E < D), (B \neq D) \}$

It is instructive for you to try to find a model for this example; try to assign a value to each variable that satisfies these constraints.

Generate-and-Test Algorithm

Enumerate:

$$\begin{split} \mathsf{D}{=} & \{A = 1, B = 1, C = 1, D = 1, E = 1\} \\ \mathsf{D}{=} & \{A = 1, B = 1, C = 1, D = 1, E = 2\} \\ \mathsf{D}{=} & \{A = 1, B = 1, C = 1, D = 1, E = 3\} \end{split}$$

We call goal(D) at each assignment to evaluate.

Generate-and-Test Algorithm

Enumerate:

We call goal(D) at each assignment to evaluate.

► In this case there are |D| = 4⁵ = 1024 different assignments to be tested. This search algorithm cannot scale up.

Generate-and-Test Algorithm

Enumerate:

. . .

We call goal(D) at each assignment to evaluate.

- ► In this case there are |D| = 4⁵ = 1024 different assignments to be tested. This search algorithm cannot scale up.
- It is unnecessarily expensive! Some constraints can be verified with partial states being generated.

Internal Structure of States

 Search algorithms are unaware of the internal structure of states.

 \rightarrow enerate successors of a state. Test whether a state is a goal.

► However, knowing a state's internal structure can help. → 4-queens: Consider a state with 2 queens in the same row. A search algorithm only knows that this is not a goal and will keep searching. But in fact, this is a dead end and we should backtrack.

Let's model the internal structure of states.

Defining a CSP

Each state contains

- A set X of variables: $\{X_1, X_2, ..., X_n\}$.
- A set D of domains: D_i is the domain for variable X_i , $\forall i$.
- A set C of constraints specifying allowable value combinations.

A solution is an assignment of values to all the variables that satisfy all the constraints.

 \rightarrow More efficient than search because the constraints will help us eliminate large portions of the search space.

Example: 4-Queens Problem

CS 486/686: Intro to AI

Lecturer: Wenhu Chen

15 / 73

▶ Variables: x_0, x_1, x_2, x_3 where x_i is the row position of the queen in column *i*, where $i \in \{0, 1, 2, 3\}$.

Assume that exactly one queen is in each column.

▶ Variables: x_0, x_1, x_2, x_3 where x_i is the row position of the queen in column *i*, where $i \in \{0, 1, 2, 3\}$.

Assume that exactly one queen is in each column.

• Domains:
$$D_{x_i} = \{0, 1, 2, 3\}$$
 for all x_i .

▶ Variables: x_0, x_1, x_2, x_3 where x_i is the row position of the queen in column *i*, where $i \in \{0, 1, 2, 3\}$.

Assume that exactly one queen is in each column.

• Domains:
$$D_{x_i} = \{0, 1, 2, 3\}$$
 for all x_i .

Constraints:

No pair of queens are in the same row or diagonal. $(\forall i (\forall j ((i \neq j) \rightarrow ((x_i \neq x_j) \land (|x_i - x_j| \neq |i - j|)))))$

For example, $((x_0 \neq x_1) \land (|x_0 - x_1| \neq 1))$

CS 486/686: Intro to AI

Q: Constraints for 4-Queens Problem

Q: Given the definitions of variables and their domains for the 4-queens problems, which constraints do we need to define?

- (A) No two queens can be in the same row.
- (B) No two queens can be in the same column.
- (C) No two queens can be in the same diagonal.
- (D) Two of (A), (B), and (C).
- (E) All of (A), (B), and (C).

Q: Constraints for 4-Queens Problem

Q: Given the definitions of variables and their domains for the 4-queens problems, which constraints do we need to define?

- (A) No two queens can be in the same row.
- (B) No two queens can be in the same column.
- (C) No two queens can be in the same diagonal.

```
(D) Two of (A), (B), and (C).
```

```
(E) All of (A), (B), and (C).
```

 \rightarrow Correct Answer: (D) Two of A, B, and C. No need to specify column constraint. Already defined separate variables for each column. Implicitly saying that we put one queen in each column.

CS 486/686: Intro to AI

Defining Constraints

There are two ways of defining a constraint.

The list/table format: Give a list/table of values of the variables that satisfy the constraints.

The function/formula format: Give a function/formula, which returns/is true if the values of the variables satisfy the constraint.

 \rightarrow In an implementation, the second format is a function, which returns true if the values satisfy the constraint.

Q: Defining Constraints as a Table

Q: Suppose that we use a 2-column table to encode the following constraint. In each row of the table, the two values of x_0 and x_2 satisfy the constraint.

The two queens in columns 0 and 2 are not in the same row or diagonal.

How many rows are there in this table?

(A) Less than 8

(B) 8

(C) 9

(D) 10

(E) More than 10

Q: Defining Constraints as a Table

Q: Suppose that we use a 2-column table to encode the following constraint. In each row of the table, the two values of x_0 and x_2 satisfy the constraint.

The two queens in columns 0 and 2 are not in the same row or diagonal.

How many rows are there in this table?

(A) Less than 8
(B) 8
(C) 9
(D) 10
(E) More than 10

 \rightarrow Correct Answer: 8

Lecturer: Wenhu Chen

Q: Defining Constraints as a Formula

Q: How should we encode the following constraint as a propositional formula?

The two queens in columns 0 and 2 are not in the same row or diagonal.

(A) $(x_0 \neq x_2)$ (B) $((x_0 \neq x_2) \land ((x_0 - x_2) \neq 1))$ (C) $((x_0 \neq x_2) \land ((x_0 - x_2) \neq 2))$ (D) $((x_0 \neq x_2) \land (|x_0 - x_2| \neq 1))$ (E) $((x_0 \neq x_2) \land (|x_0 - x_2| \neq 2))$

CS 486/686: Intro to AI

Q: Defining Constraints as a Formula

Q: How should we encode the following constraint as a propositional formula?

The two queens in columns 0 and 2 are not in the same row or diagonal.

(A)
$$(x_0 \neq x_2)$$

(B) $((x_0 \neq x_2) \land ((x_0 - x_2) \neq 1))$
(C) $((x_0 \neq x_2) \land ((x_0 - x_2) \neq 2))$
(D) $((x_0 \neq x_2) \land (|x_0 - x_2| \neq 1))$
(E) $((\mathbf{x}_0 \neq \mathbf{x}_2) \land (|\mathbf{x}_0 - \mathbf{x}_2| \neq 2))$

 \rightarrow Correct Answer: (E) $((x_0 \neq x_2) \land (|x_0 - x_2| \neq 2))$

CS 486/686: Intro to AI

Lecturer: Wenhu Chen

CS 486/686: Intro to AI

The Idea of Arc Consistency

$x_0 = 0$ and $x_1 = 2$ do not lead to a solution. Why?

Handling Different Types of Constraints

Consider binary constraints only.

► How should we handle unary constraints?
→ Remove invalid values from variable domain

How should be handle constraints involving 3 or more variables?

 \rightarrow Convert them to binary constraints

Notation for an Arc

 \blacktriangleright X and Y are two variables. c(X, Y) is a binary constraint.

$$D_X \quad \underbrace{X} \quad \underbrace{\langle X, c(X,Y) \rangle}_{c(X,Y)} \quad \underbrace{\langle Y, c(X,Y) \rangle}_{Y} \quad D_Y$$

\$\langle X, c(X, Y) \rangle\$ denotes an arc.
 X is the *primary variable* and Y is the *secondary variable*.

The Arc Consistency Definition

Definition (Arc Consistency)

An arc $\langle X, c(X, Y) \rangle$ is arc-consistent if and only if for every value $v \in D_X$, there is a value $w \in D_Y$ such that (v, w) satisfies the constraint c(X, Y).

Q: Applying The Arc Consistency Definition

Q: Consider the constraint X < Y. Let $D_X = \{1, 2\}$ and $D_Y = \{1, 2\}$. Is the arc $\langle X, X < Y \rangle$ consistent?

(A) Yes.

(B) No.

(C) Maybe?

(D) I don't know.

Q: Applying The Arc Consistency Definition

Q: Consider the constraint X < Y. Let $D_X = \{1, 2\}$ and $D_Y = \{1, 2\}$. Is the arc $\langle X, X < Y \rangle$ consistent?

(A) Yes.

(B) No.

(C) Maybe?

(D) I don't know.

 \rightarrow Correct answer is (B) No. We can remove 2 from D_X .

Backtracking Search

The Arc Consistency Definition

The AC-3 Arc Consistency Algorithm

Combining Backtracking and Arc Consistency

CS 486/686: Intro to AI

The AC-3 Arc Consistency Algorithm

Algorithm 7 The AC-3 Algorithm

- 1: put every arc in the set S.
- 2: while S is not empty do
- 3: select and remove $\langle X, c(X,Y) \rangle$ from S
- 4: remove every value in D_X that doesn't have a value in D_Y that satisfies the constraint c(X, Y)
- 5: **if** D_X was reduced **then**
- 6: **if** D_X is empty **then return** false
- 7: for every $Z \neq Y,$ add $\langle Z, c'(Z,X) \rangle$ to S return true

Why do we need to add arcs back to S?

Q: After reducing a variable's domain, we may need to add arcs back to S. Why?

A: Reducing a variable's domain may cause a previously consistent arc to become inconsistent.

Does the order of removing arcs matter?

Does the order of removing arcs matter?

 $\rightarrow \text{No}.$

Does the order of removing arcs matter?

 $\rightarrow \text{No.}$

▶ Three possible outcomes of the arc consistency algorithm:

Does the order of removing arcs matter?

 $\rightarrow \text{No}.$

 \rightarrow

Three possible outcomes of the arc consistency algorithm:

1. A domain is empty. No solution.

2. Every domain has 1 value left. Found the solution without search.

3. Every domain has at least 1 value left and some domain has multiple values left. Need search to find a solution.

Is AC-3 guaranteed to terminate?

 $\rightarrow \text{Yes}.$

Is AC-3 guaranteed to terminate?

 \rightarrow Yes.

What is the complexity of AC-3?

Is AC-3 guaranteed to terminate?

\rightarrow Yes.

• What is the complexity of AC-3? \rightarrow Time complexity: $O(cd^3)$. n variables, c binary constraints, and the size of each domain is at most d. Each arc (X_k, X_i) can be added to the queue at most d times because we can delete at most d values from X_i . Checking consistency of each arc can be done in $O(d^2)$ time. Learning Goals

Examples of CSP Problems

Formulating a CSP

Solving a CSP

Backtracking Search

The Arc Consistency Definition

The AC-3 Arc Consistency Algorithm

Combining Backtracking and Arc Consistency

CS 486/686: Intro to AI

Lecturer: Wenhu Chen

Combining Backtracking and Arc Consistency

- 1. Perform backtracking search.
- 2. After each value assignment, perform arc consistency.
- 3. If a domain is empty, terminate and return no solution.
- 4. If a unique solution is found, return the solution.
- 5. Otherwise, continue with backtracking search on the unassigned variables.

3 X -

 x_2 's domain is empty after AC-3 arc consistency algorithm, therefore, we can directly trace back.

- Remove the 0 _ _ branch.
- Traceback to the root, and then start searching with 1 _ _ _.
- We run AC-3 arc consistency algorithm, found an assignment with each domain containing one value!
- The only solution is found!

Combination

- Perform standard backtracking search.
- ► Whenever a variable has been assigned.
 - Select several unassigned variables.
 - Run arc-consistency algorithm on the unassigned variables.
 - Apply AC-3 to propagate the constraints from this assignment
 - if no value is found, backtrack to the previous assigned variable.

Implementation of Backtrack+AC-3

```
queue = [(Xi, Xj) for Xi in csp.variables for Xj in csp.neighbors[Xi]]
   while queue:
       (Xi, Xj) = queue.pop(0)
        if revise(csp, Xi, Xi):
           if len(csp.domains[Xi]) == 0:
            for Xk in csp.neighbors[Xi] = {Xj}:
               queue.append((Xk, Xi))
def revise(csp, Xi, Xj):
   revised = False
   for x in csp.domains[Xi]:
        if not any(csp.constraints(Xi, x, Xj, y) for y in csp.domains[Xj]):
            csp.domains[Xi].remove(x)
            revised = True
    return revised
def backtrack(csp, assignment):
    if len(assignment) == len(csp.variables):
        return assignment
   var = select unassigned variable(csp, assignment)
   for value in csp.domains[var]:
        if is consistent(csp, assignment, var, value):
            assignment[var] = value
           local csp = csp.copv()
           local_csp.domains[var] = {value}
           if ac3(local csp):
               result = backtrack(local_csp, assignment)
               if result:
                   return result
            assignment.pop(var)
def solve_csp(csp):
   ac3(csp)
   return backtrack(csp, {})
```
